

Differences in warehouse and distribution facility budgets and their operational requirements, dictate the level of work allowed prior to applying a warehouse floor striping solution, which is why unprepared methods are often more appropriate than the durable alternatives.

Direct epoxy floor striping is the practice of applying a paint system to a concrete surface without prior work to improve adhesion. Unfortunately, the performance of this type of floor marking is limited, though still popular none the less. It is less durable and can be altered or made more hardwearing later once the layout and operational flow of the facility is established.

As with all of our warehouse striping methods, we select the most appropriate paint system for your facility and traffic needs, we only use the very best available. ASG Services is not restricted to any one paint supplier and we explore every option before making our recommendation to you.

Our most popular and most commonly used paint system is epoxy.

Even though this method of floor marking is on an 'unprepared' surface, we do ensure the concrete surface is free from dirt, dust and debris before applying the paint. We may need to use a floor cleaner, solvent and/or other materials to clean the floor, or request the customer does this first.

Two paint application methods are possible with this, which are sprayed and rolled lines. We would recommend sprayed to help reduce time needed and therefore cost and disruption.

We are happy to discuss your facility and plans as well as arranging a site visit with you, which may help address any unforeseen issues.

Recommended for use with

Light forklift traffic

Medium forklift traffic

Heavy forklift traffic
